Abstract: The aim of this paper is to investigate localization accuracy of ultra wideband (UWB) radar with a minimal antenna array taking in the account complexity of the real environment (extended and multiple targets, presence of wall or other obstacle in the line of sight, practical restrictions of antenna setting). Simulation-based results show how the localization accuracy depends on the radar range resolution, deployment of the radar antennas and the accuracy of ranges estimated between transmitting antenna-target-receiving antenna. As the output, the distributions of the average localization errors in the monitored area are obtained. Their correctness is demonstrated by processing of the signals acquired by two M-sequence UWB radars with different range resolution and coverage.

Keywords: localization accuracy; UWB radar; antenna setting; complex environment; TOA measurement

1 Introduction

Detection and localization of people by an ultra wideband (UWB) radar has numerous practical applications including anti-terror or anti-drug operations, victim search and rescue following an emergency or interior monitoring for aged people helping to ensure their health and safety [5], [16].

The minimal amount of radar antennas required for passive (uncooperative) target localization in two dimensional (2D) space by means of trilateration principles is one transmitting antenna (T_x) and two receiving antennas (R_{x_1} , R_{x_2}). UWB radars with such small antenna array usually utilize less complex signal processing, are cheaper and more flexible during measurement than the radars with multiple antennas or the sensor networks. On the other hand their localization accuracy and maximal range are limited.

The localization accuracy performance is in the literature evaluated from many aspects. In most cases, the Cramér Rao Lower Bound (CRLB) is used to assess the localization accuracy which can be attained with the available measurement set, e.g. [6], [7], [12], [17]. From them, [7] presents an analysis of target localization accuracy, attainable by the use of multiple-input multiple-output (MIMO) radar systems, configured with multiple transmit and receive sensors, widely distributed over an area. In [12] the authors investigate and compare the precision of selected localisation methods with respect to the wireless sensor network (WSN) geometry and highly inaccurate distance measurements. [17] analyzes the achievable accuracy of a new localization system, designed by the authors, using time-difference-of-arrival (TDOA) measurements by covering the sources for time measurement errors like thermal noise, timing jitter, and multi-path propagation. The authors of [6] interestingly stated that the CRLB is more pertinent for outdoor applications where low-scattering channels prevail but not necessarily so for strong-scattering channels that characterize dense-multipath indoor environments in emerging commercial applications of UWB radios.

In latter papers, even derivation of a new CRLB based on a distance-dependent noise variance modelling is introduced for time-of-arrival (TOA) and TDOA measurements in [8] and [9], respectively. The authors demonstrate that the distance-dependent variance model impacts the derivation of the Fisher information matrix, eventually leading to a CRLB different from the existing derivations.

The localization accuracy can be evaluated by means of simulation results, too [1], [19]. For example in [19], the accuracy enhancement for 3D indoor localization has been demonstrated with the use of 4, 5, and 6 base stations. [1] deals with the 2D indoor localization accuracy of the short-range UWB radar acquiring TOA measurement with a minimal antenna array, what is exactly application on which we focus. In [1], though, the accuracy was investigated under ideal conditions, i.e. a pinpoint target, no multiple reflections, no additional noise, etc. It was demonstrated that the quantization effect by itself results in the localization error up to 2.5 m, the largest target position estimation errors are located along the straight lines between Tx and all Rx antennas and that the ideal distance between antennas of UWB radar system with the range resolution of 1.7 cm and coverage up to 8.5 m should be set to 5 m.

However, in a real measurement it is not very functional to have the antennas so far each other. Many times the character of monitored area does not allow it, e.g. the short length of wall through which the targets are tracked. More important is flexibility loss of the portable device and loss of radar data similarity resulting from small and symmetric distance between antennas utilizable for data association. These practical restrictions of antenna setting together with presence of wall or other obstacle in the line of sight as well as challenging nature of human targets create a complex environment which should be taken into account while investigating the localization accuracy of the UWB radar. It is the main goal of

this paper. For that purpose the simulation based considerations, extending the ideas and results provided in [1], will be given in Section 2. Consequently they will be validated by the experimental results provided in Section 3. Finally, the concluding remarks will be summarized in the last section.

2 Localization Accuracy

To understand the distribution of average localization errors inside a monitored area two things need to be explained. The first one relates to regular organization of the estimated positions which is described in Section 2.1. The second topic is about manifestation of measurement and processing errors further discussed in Section 2.2. After that the localization accuracy of UWB radar system with small antenna array will be shown in the form of localization error maps in Section 2.3.

2.1 Rays Formed from Estimated Locations

As the considered UWB radar system works with the minimal amount of radar antennas (Tx , Rx_1 , Rx_2), the target locations are estimated by the direct method of localization [1]. The input data to this algorithm has a form of time-of-arrival (TOA) of signals propagating between Tx -target- Rx_k , $k=1,2$. The correctly estimated and associated TOA couples from both receivers produce, after localization process, the true target positions and no false targets (ghosts). On the basis of the triangle inequality arising from the antenna layout and an arbitrary target position, difference between TOA estimated from both receivers and belonging to the same target fulfil the following inequality:

$$|TOA_1 - TOA_2|c \leq 2d \quad (1)$$

where TOA_k represents TOA estimated by the receiver Rx_k , c is the speed of light and $d = dist(Tx, Rx_1) = dist(Tx, Rx_2)$ is the distance between adjacent antennas. The foundation of (1) is illustrated in Figure 1 and in detail derived in [15].

Figure 1

Scheme of the layout of the radar antennas and the targets in a monitored area. Target T_1 located on x -axis has TOA difference equal to $2d/c$, target T_2 located on y -axis has TOA difference equal to 0 and target T_3 located neither on x -axis nor on y -axis has TOA difference lesser than $2d/c$.

If $2d$ is small (e.g. less than 1 m), the TOA difference can be used for simple, yet efficient data association [15]. Moreover if $2d$ is divided by the theoretical maximal radar range resolution $S_r = \frac{c}{2f}$ and properly adjusted according the relation

$$N = \text{int}\left(\frac{2d}{S_r}\right) + 1 \quad \text{if } \text{int}\left(\frac{2d}{S_r}\right) \text{ is even number,} \quad (2)$$

$$N = \text{int}\left(\frac{2d}{S_r}\right) \quad \text{if } \text{int}\left(\frac{2d}{S_r}\right) \text{ is odd number} \quad (3)$$

(f – radar frequency, $\text{int}(x)$ - the integer part of x),

then the quantity N represents number of TOA couples which meets (1). Consequently, if from these TOA couples are computed target locations, they are regularly spread in the radar coverage on the N rays rising from the segment between Rx_1 - Tx - Rx_2 (Figure 2). The distance between the adjacent positions located on the same ray is equal to the range resolution S_r and their total number on the ray corresponds to the total number of samples (chips) of the radar signal.

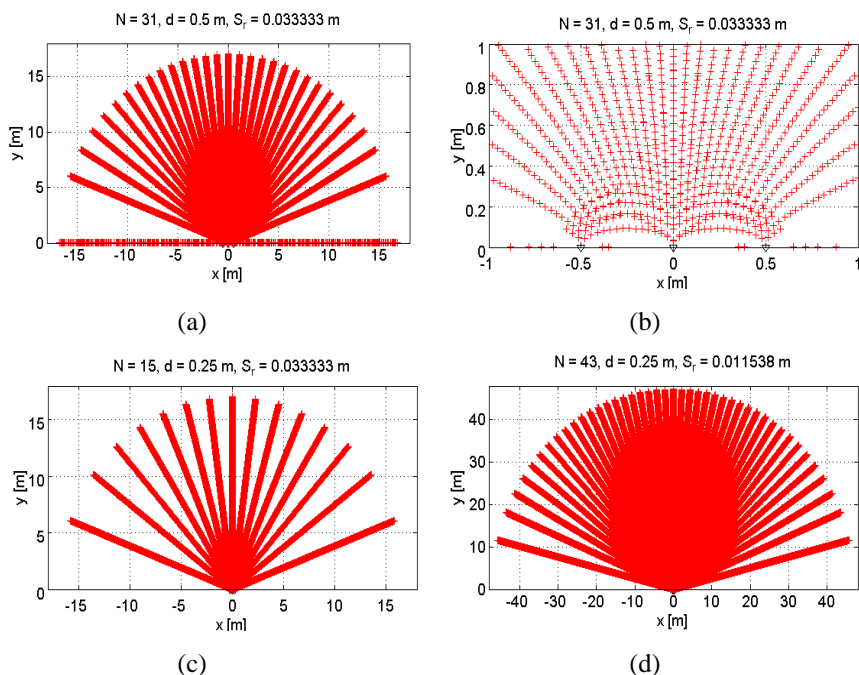

Figure 2

Rays formed from estimated locations: (a) $N=31$ obtained for $d=0.5 \text{ m}$ and $S_r=0.0333 \text{ m}$, (b) zoom in the segment between Rx_1 - Tx - Rx_2 , (c) $N=15$ obtained for $d=0.25 \text{ m}$ and $S_r=0.0333 \text{ m}$, (d) $N=43$ obtained for $d=0.25 \text{ m}$ and $S_r=0.0115 \text{ m}$

From (2) and (3) can be easily implied that N increases with bigger d (Figure 2(c) vs. 2(a)) and finer S_r (Figure 2(c) vs. 2(d)). From Figure 2 can be also seen that the biggest localization errors are in the surrounding of the x -axis and at the end of coverage area when the rays retreat from each other.

The relation between the number of rays N , the antenna distance d and the radar range resolution S_r is illustrated in Figure 3. It can be observed from there that notable increase of N is achievable with $S_r = 0.01 \text{ m}$. The values $S_r \geq 0.07 \text{ m}$ provide almost comparable values of N for $d \in \langle 0, 1 \rangle \text{ m}$. It naturally holds - the larger N , the better localization accuracy.

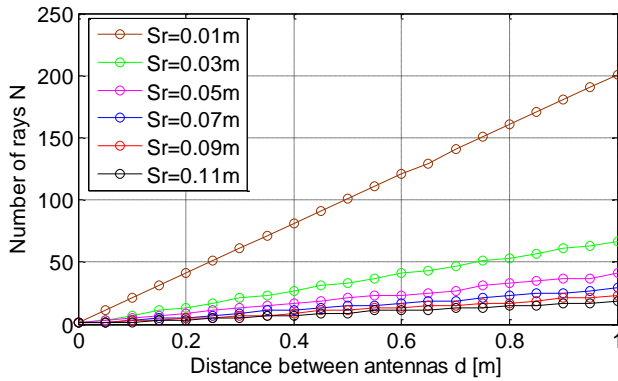

Figure 3

The relation between the number of rays N , the antenna distance d and the radar range resolution S_r .

2.2 Measurement Errors and Processing Errors

The localization accuracy is influenced by measuring and processing errors. According [3], the measurement errors can be classified to following groups:

- S/N -dependent random measurement error,
- random measurement error having fixed standard deviation, due to noise sources in the latter stages of the radar receiver,
- bias error associated with the radar calibration and measurement process,
- errors due to radar propagation conditions,
- errors from interference sources such as radar clutter and radar jamming signals.

These errors depend mostly on properties of employed UWB radar system and can be partially reduced by a careful calibration.

The sources of processing errors accumulate with a complexity of the environment. The localization errors are particularly massive in the cases when is needed to monitor crowded full-furnished areas containing strong reflectors, moreover through some obstacle (e.g. wall or walls) with unknown parameters. All such conditions influence the target range estimation and consequently the target localization accuracy. Considering UWB radar signal processing aimed at localization of people, the following error sources need to be especially treated within the particular processing phases:

- time zero setting during pre-processing phase – incorrect finding of the first bigger peak indicating crosstalk results in a bias range error [18],

- loss of reflections from motionless or mutually shadowed persons during background subtraction phase – missing data for localization [10],
- evaluation of a strong reflector gradually shadowed by a moving person as another target during detection phase – false target detection [11],
- replacement of extended targets (human body has radar cross section larger than the UWB radar range resolution) by simple targets (one value of time of arrival (TOA) on the path $Tx\text{-}target\text{-}Rx$ for every target) and their association through all receivers during TOA estimation phase – incorrect replacement results in target range errors and incorrect association causes generation of the ghost targets [15],
- wall parameter estimation and not exact methods of correction during wall effect compensation phase – bias range error due to unknown wall parameters or residual error due to approximate compensation methods [14],
- arrangement of the computed locations on the limited number of rays during localization phase – localization errors if target is located outside the rays (Section 2.1),
- distinction of crossing targets, slow change of direction for fast manoeuvring targets and track maintenance during tracking phase – despite of many advantages of tracking systems, improper setting of tracking parameters can lead to aggravation of the localization results [2].

Taking into account all the measuring and processing errors occurring in the complex environment, it is realistic to expect the target range error as several multiples of the maximal range resolution. Said by other quantities, TOA is estimated with error of few T_s , where $T_s = 1/f$ represents a sample period.

Figure 4 illustrates the increasing of localization error with the increasing of TOA error given by the standard deviation of a Gaussian distribution expressed in multiple of T_s . The figure has form of an empirical Cumulative Distribution Function (CDF). Here, CDF is defined by $CDF(E) = P(E \leq e)$ where $P(E \leq e)$ is a probability that the localization error E is less than or equal to e . The CDF in Figure 4 were calculated for the antenna distance $d = 0.5m$, the range resolution $S_r = 0.0333m$ and the standard deviations $STD \in \{0, 1T_s, 2T_s, 3T_s, 4T_s\}$. The case $STD = 0$ means that TOA was estimated, except for the quantization error, accurately. Then, the localization errors observable in Figure 4 for the red curve line results only from limited number of rays formed from estimated locations. The maximal error around 6 m appertains to the positions located near the x -axis what corresponds with Figure 2(a). From the red CDF from Figure 4 can be also seen that 90% of all estimated locations has localization error less than 2 m. The increasing of the standard deviation leads to increasing of the maximal

localization error gradually up to 26 m. The localization error for 90% of all estimated locations rises with every consequent value of STD approximately about 2 m (Figure 4).

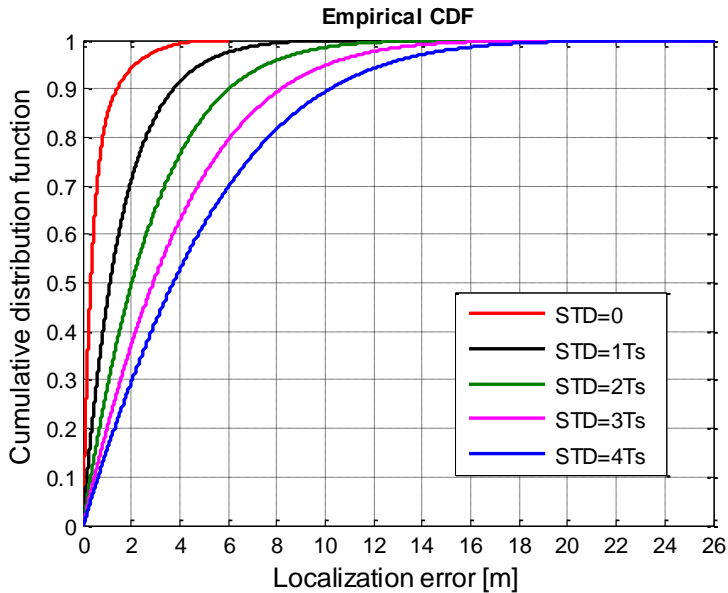

Figure 4

Illustration of the localization error increasing with the increasing of TOA error given by the standard deviation of a Gaussian distribution expressed in multiples of the sample period T_s by means of the cumulative distribution function

2.3 Maps of Average Localization Errors

Distribution of the localization errors in a monitored area can be demonstrated through the maps of average localization errors. The map is created in the following steps:

- the monitored area is divided to subregions,
- from every subregion is randomly generated K positions,
- for them is calculated exact TOA as round trip time between Tx -the k th position- Rx_i for $k=1,2,\dots,K$ and $i=1,2$,
- every exact TOA is rounded (quantization error) and increased about the expected STD of a Gaussian distribution expressed in multiples of T_s (measuring and processing error),
- from the couples of such TOA are computed the position estimates,

- the difference between the true and estimated position express the localization error,
- for every subregion is computed the average localization error,
- finally, all the subregions are depicted in a common map where according to color is possible to distinguish regions with different localization errors.

The illustration of three various visual display of the localization error distribution is given in Figure 5 and Figure 6. The first figure depicts accumulation of the localization errors under the same scale of colours expressing the average error from interval $\langle 0,10 \rangle m$. The maps from Figure 5(a) to Figure 5(f) demonstrate the extension of the localization error due to increasing of TOA error. The results complement the information provided by the CDF from Figure 4.

Figure 6 represents a decrease of the localization error depending on the increasing of the distance between antennas. The colour scale adapts to maximal attained localization error. The maps from the first column are depicted also in the form of contour maps in the second column of Figure 6. The contour maps provide a clear understanding of the mutual relation between a given deployment of radar antennas and the achievable accuracy at various target locations. From Figure 6 can be observed the changing shape of the most precise areas.

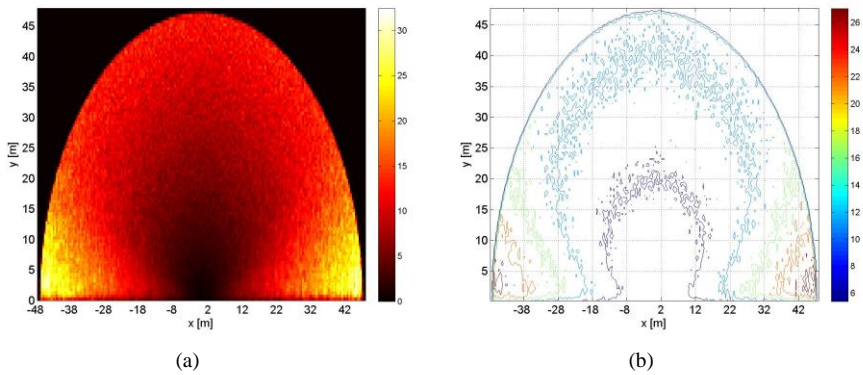

Figure 5

The maps of average localization errors obtained for $d=0.5$ m, $Sr=0.0333$ m and changing TOA error expressed as STD of a Gaussian distribution expressed in multiples of T_s (a) $STD=0$, (b) $STD=1T_s$, (c) $STD=2T_s$, (d) $STD=3T_s$, (e) $STD=4T_s$, (f) $STD=5T_s$.

Figure 6

The maps of average localization errors obtained for $Sr=0.0115$ m, $STD=3T_s$, and changing d ($d=0.1$ m, (b) the contour map for $d=0.1$ m, (c) $d=0.5$ m, (d) the contour map for $d=0.5$ m, (e) $d=1$ m, (f) the contour map for $d=1$ m

3 Experimental Results

The validation of presented simulation results concerning the localization accuracy of UWB radar operating in complex environment is demonstrated by processing of the signals acquired by two M-sequence UWB radars with different range resolution and coverage [4], [16]. The first UWB radar system, depicted in Figure 7(a), has the range resolution 0.0115 m and coverage of 47 m. The remaining basic parameters are 13 GHz chip clock rate and 4095 impulse response samples regularly spread over 315 ns. During measurement, the radar was equipped with one transmitting and two receiving opened horn antennas (Figure 7(a)).

The second M-sequence UWB radar, depicted in Figure 7(b), has the range resolution 0.0333 m and coverage of 17 m. The remaining basic parameters are 4.5 GHz chip clock rate and 511 impulse response samples regularly spread over 114 ns. During measurement, the radar was equipped with one transmitting and two receiving closed horn antennas (Figure 7(b)).

Figure 7

M-sequence UWB radars with: (a) the range resolution 0.0115 m and coverage of 47 m, (b) the range resolution 0.0333 m and coverage of 17 m

3.1 Measurement I

The first measurement was realized without an obstacle in the line of sight. The M-sequence radar with the coverage of 47 meters was located together with antennas in the long corridor. The distance between antennas was set to 0.42 m, because the area was narrow, with Tx between Rx₁ and Rx₂. The measurement scenario was simple – a person was walking from the position in front of Tx 40 m straight and then back with short stopping every 5 m.

The localization results obtained by the signal processing procedure for the detection, localization and tracking of moving targets, described in [13], are depicted in Figure 8(a). Here can be observed that despite of the scenario simplicity the localization errors reach the values above the 20 m. However, such results are consistent with the expected distribution of average localization errors represented in Figure 8(b).

The localization error map was computed for the parameters $S_r=0.0115\text{ m}$, $d=0.42\text{ m}$ and $STD=9T_s=0.69\text{ ns}$. The value of STD was found for the used M-sequence UWB radar experimentally on the basis of various measurements. According the environment complexity, average TOA errors recomputed to ranges reach the values between 0.2 m to 0.3 m for human targets. It corresponds with $STD \in \langle 9T_s, 13T_s \rangle$ for $T_s=0.0769\text{ ns}$. As the considered measurement was realized without an obstacle in the line of sight, $STD=9T_s$.

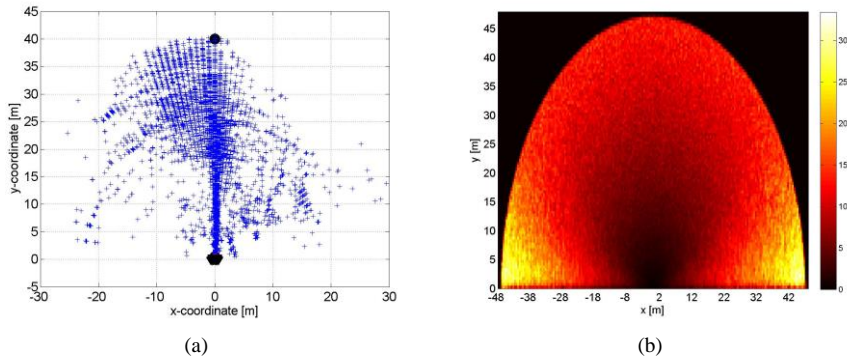

Figure 8

Measurement I: (a) estimated target positions, (b) expected localization errors for the parameters

$$S_r=0.0115 \text{ m}, d=0.42 \text{ m}, STD=9T_s=0.69 \text{ ns}$$

3.2 Measurement II

The second measurement was more challenging. The M-sequence UWB radar with the coverage of 17 m was located behind 0.17 m thick concrete wall (Fig. 9). The distance between adjacent antennas was set to 0.38 m (maximal distance enabled by the used tripod), 0.14 m from the wall (Figure 9(a)). The monitored area was short corridor with a staircase depicted in Figure 9(b). During measurement, a person was walking along the corridor up the stairs and then back through the reference positions P1-P2-P1 marked in Figure 9(c).

The localization results obtained by the same signal processing procedure as in the first measurement are depicted in Figure 9(d). As the relative permittivity of the wall was not known, the wall effect compensation phase was omitted. As result, the bias error shifted all the estimated positions further from the radar antennas

(a)

(b)

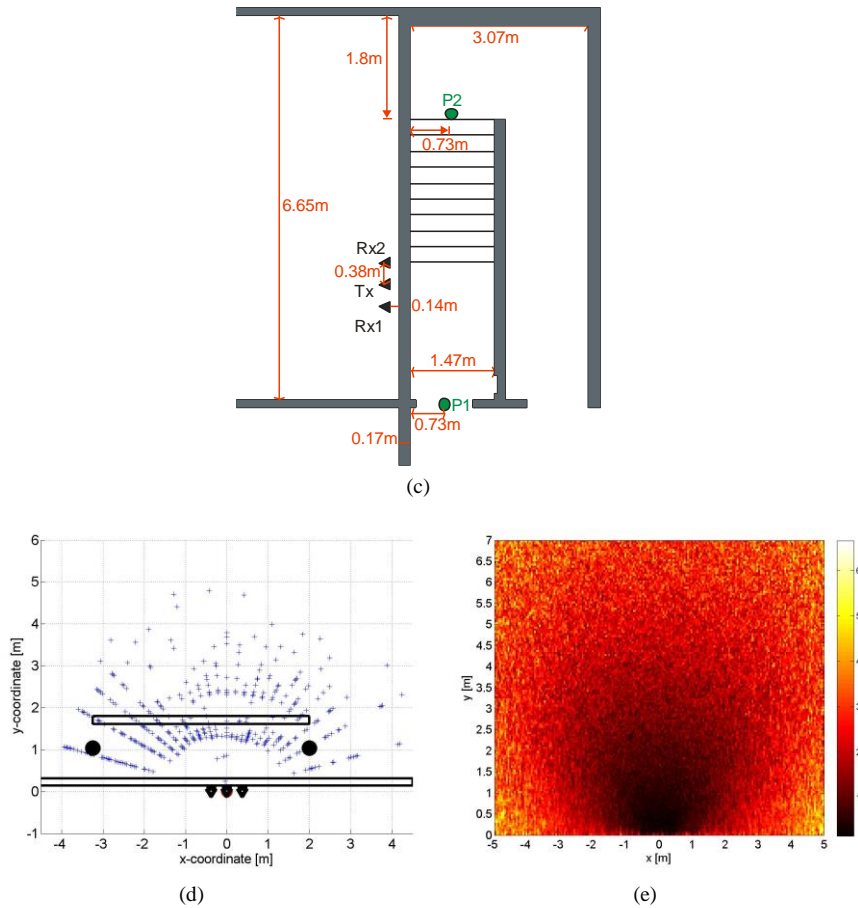

Figure 9

Measurement II: (a) the antenna deployment behind the wall, (b) interior of monitored area, (c) scheme of the measurement scenario, (d) estimated target positions, (e) expected localization errors for the parameters $S_r=0.0333\text{ m}$, $d=0.38\text{ m}$, $STD=5T_s=1.11\text{ ns}$

(Figure 9(d)). In addition, the movement near by the rear wall caused the multiple reflections visible in Figure 9(d) for y -coordinate above 2 m.

The best localization accuracy of the target trajectory was achieved in the area 1 m to the left and to the right from Tx. The further parts of target trajectory was estimated with the error higher than 1 m, whereas when the person was walking up and down the stairs the localization error exceeded 2 m (Figure 9(d)).

These results correspond with the expected distribution of average localization errors represented in Figure 9(e). The localization error map was computed for the parameters $S_r=0.0333\text{ m}$, $d=0.38\text{ m}$ and $STD=5T_s=1.11\text{ ns}$. Analogous to the

previous case, for the used M-sequence UWB radar holds that for human targets the average TOA errors recomputed to the ranges reach the values between 0.2 m to 0.3 m depending up the environment complexity. It corresponds with $STD \in \langle 3T_s, 5T_s \rangle$ for $T_s = 0.222ns$. As the considered measurement was realized through concrete wall with unknown parameters, the standard deviation of the TOA error was chosen $5T_s$.

Finally, the tracking results from both considered scenarios are depicted in Figure 10. It can be seen from there that the correctly adjusted tracking system can considerably decrease the localization error.

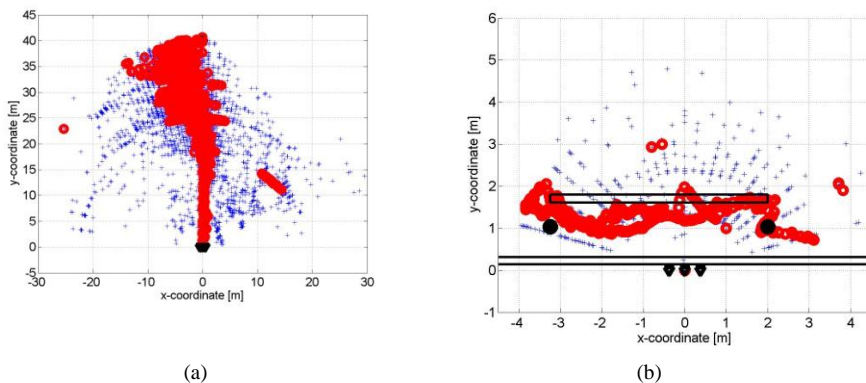

Figure 10

The target track estimated for scenario from: (a) measurement I, (b) measurement II

Conclusions

The simulation and experimental results presented in this paper provide practical view on the localization accuracy of UWB radars with minimal antenna array. The obtained maps of the localization errors enable to plan the emplacement of the antenna system depending on the monitored area in advance. They also help to decided about the suitability of the chosen UWB radar for some considered application. The introduced investigation of the localization accuracy taking into account the complexity of the monitored environment can serve as the basis for the analysis of localization accuracy for a sensor network consisted from independent UWB radar systems.
